

Project Proposal: Student Registration System

1. Introduction

Education institutions often face challenges in maintaining accurate and organized student records. Traditional paper-based systems are time-consuming, prone to errors, and difficult to update. To overcome these limitations, a web-based Student Registration System will be developed. This system will allow administrators to register students, store their personal and academic information, and retrieve data efficiently. By using modern web technologies such as HTML, CSS, PHP, and MySQL, the project aims to create a platform that is both functional and visually appealing.

The system will not only serve as a digital repository of student information but also as a learning project for understanding how web applications are designed, developed, and deployed.

2. Objectives

The main objectives of the project are:

Develop a user-friendly interface that makes data entry simple and intuitive.

Digitize student records to reduce dependency on manual paperwork.

Provide quick access to information through search and filtering features.

Minimize human errors by implementing validation during data entry.

Enhance technical skills by learning and applying web development technologies.

3. Problem Statement

Currently, many institutions rely on manual systems such as registers, files, and spreadsheets to manage student data. These methods are inefficient because:

- a. Data retrieval takes a long time.
- b. Records are vulnerable to loss or damage.
- c. Errors in manual entry are common.
- d. Updating information requires repetitive work.

Therefore, an automated Student Registration System is necessary to ensure accuracy, efficiency, and reliability in handling student data.

4. Methodology

- a. The project will follow a structured development methodology:
- b. **Requirement Analysis** – Identify the needs of the system, including data fields (name, roll number, photo, etc.) and functionalities (CRUD operations).
- c. **System Design** – Create database schema and design user interface layouts.
- d. **Development** – Implement the system using HTML, CSS for front-end, PHP for server-side logic, and MySQL for database management.
- e. **Testing** – Verify that all modules work correctly, including data validation, photo upload, and search functionality.
- f. **Deployment** – Host the system locally using XAMPP and prepare for possible online deployment.

5. Requirements

1. Hardware: A computer with internet connectivity.
2. Software:
 - a. XAMPP (for Apache server and MySQL database)
 - b. Visual Studio Code (for coding)
 - c. Web browser (for testing and running the application)

6. Expected Outcome

The expected outcome of the project is a functional Student Registration System with the following features:

- a. Add, update, delete, and view student records.
- b. Upload and store student photographs.
- c. Search and filter student data quickly.
- d. Provide a clean and modern user interface.

This system will save time, reduce workload, and improve the accuracy of student data management.

7. Conclusion

The system will improve data management and reduce manual workload.

Database Design

Field	Type	Description
Id	INT	Primary Key
Name	VARCHAR(100)	Student Name
Email	VARCHAR(100)	Email
Phone	VARCHAR(20)	Phone
Course	VARCHAR(50)	Course

Timeline:

Task	Duration
Planning	1 Day
Design	1 Day
Development	2 Day
Testing	1 Day
Final Submission	1 Day
